Abstract

Mental Retardation (MR) is a genetic disorder manifested in significantly below average overall intellectual functioning and deficits in adaptive behaviour. It is a particular state of functioning that begins in childhood and is characterized by decreased intelligence and adaptive skills and also is the most common developmental disorder, often missed by clinicians. The condition is present in 2 to 3 percent of the population, either as an isolated finding or as part of a syndrome or broader disorder.

Looking at varies studies it was concluded that the oral health situation of these groups must be improved and a suitable system devised for delivery of preventive measures. Special consideration must be given to improving the oral health of these groups. Oral health should be included in each child’s individual health care plan with oral health promotion programmes aimed specifically at special needs schools and their parents. Children should be instructed to clean their teeth twice a day and oral hygiene should be practised at school and supervised by teachers. There should be a provision for in-service training for teachers, school staff and parents on how to promote good oral health specifically for these children with disabilities.

Introduction

Mental Retardation (MR) is a genetic disorder manifested in significantly below average overall intellectual functioning and deficits in adaptive behaviour. Mental retardation is a particular state of functioning that begins in childhood and is characterized by decreased intelligence and adaptive skills and also is the most common developmental disorder [1,2]. MR in young children is often missed by clinicians. The condition is present in 2 to 3 percent of the population, either as an isolated finding or as part of a syndrome or broader disorder. It is not a medical disorder, nor a mental disorder. It reflects the “fit” between the capabilities of individuals and the structure and expectations of their environment [1].

AAMD definition of mental retardation [3]

Mental retardation is a disability characterized by significant limitations both in intellectual functioning and in adaptive behavior as expressed in conceptual, social, and practical adaptive skills [3].

The AAMD classifies retardation into four categories according to intelligence quotient (IQ):

Epidemiology of mental retardation

The disabled comprise a substantial section of the community and it is estimated that there are about 500 million people with disabilities worldwide. The recent National Sample Survey Organization (NSSO: 2003) report no. 485(58/26/1) suggests that the number of disabled persons in the India is estimated to be 18.49 million, accounting for about 1.8% of the total population, while the mentally retarded population amounted to 0.44 million individuals [15].

Causes of mental retardation

Are numerous and include genetic and environmental factors. Diagnosis is highly dependent on a comprehensive personal and family medical history, a complete physical examination and a careful developmental assessment of the child. These will guide appropriate evaluations and referrals to provide genetic counselling, resources for the family and early intervention programs for the child [5].

It is also believed that behavioural or societal factors such as poverty, malnutrition, maternal drug and alcohol use, as well as severe stimulus deprivation can contribute to MR [6]. Unfortunately, in approximately 30 to 50 percent of cases, the etiology is not identified even after thorough diagnostic evaluation [4,7].

Some persons have a congenital malformation of the brain; others had damage to the brain at a critical period in pre- or postnatal development. Acquired causes of retardation include neardrowning, traumatic brain injury and central nervous system malignancy. The most common cause of MR in industrialized nations is fetal alcohol syndrome with an incidence rate of 1 in 100 births. The second leading known cause of MR is Down syndrome, or trisomy 21, with an incidence rate of 1 in 800-1,000 births [8].

1. Genetics conditions

A number of single-gene disorders result in MR. Many of these are associated with atypical or dysmorphic physical characteristics such as fragile X syndrome, neurofibromatosis, tuberous sclerosis, Noonan’s syndrome and Cornelia de Lange’s syndrome [9,10]. Other genetic conditions include Phelan-McDermid syndrome (22q13del), Mowat-Wilson syndrome, genetic ciliopathies. In the rarest of cases, abnormalities with the X or Y chromosome may also cause disability. 48, XXXX and 49, XXXXX syndrome affect a small number of girls worldwide, while boys may be affected by 47, XYY, 49, XXXXY, or 49, XXXYY.

2. Prenatal problems

MR can result when the fetus does not develop inside the mother properly. Moreover, prenatal causes include congenital infections such as cytomegalovirus, toxoplasmosis, herpes, syphilis, rubella and humanimmunodeficiency virus; prolonged maternal fever in the first trimester; exposure to anticonvulsants or alcohol; and untreated maternal Phenylketonuria (PKU). Complications of prematurity, especially in extremely low-birth-weight infants, or postnatal exposure to lead can also cause MR [11].

3. Perinatal problems

Perinatal causes involve late pregnancy (complications of pregnancy, diseases in mother such as heart and kidney disease and diabetes and placental dysfunction), during delivery (labour) (severe prematurity, very low birth weight, birth asphyxia, difficult or complicated delivery and birth trauma), neonatal (septicaemia, severe jaundice, hypoglycemia [13]).

4. Postnatal problems (in infancy and childhood)

Postnatal problems can be brain infections such as tuberculosis, Japanese encephalitis, and bacterial meningitis, head injury, chronic lead exposure, severe and prolonged malnutrition and gross understimulation [14].

5. Metabolic disorders

Metabolic disorders are another possible cause of MR. In some cases (e.g., PKU, hypothyroidism), retardation is preventable with early treatment. Other disorders (e.g., mucopolysaccharidosis, spingolipidoses) are less responsive to early intervention.

6. Exposure to certain types of disease or toxins

Diseases like whooping cough, measles, or meningitis and poisoning like lead or mercury can cause MR if medical care is delayed or inadequate.

7. Iodine deficiency (cretinism)

Iodine deficiency affecting approximately 2 billion people worldwide is the leading preventable cause of MR in developing countries where iodine deficiency is endemic.

<td>1</td>
<td>Bratel J, Berggren U, Hirsch JM. Electric or manual toothbrush? A comparison of the oral health of mentally handicapped adults. Clin Prev Dent. 1988; 10: 23-26. [15].</td>
<td>The effect of electric versus manual toothbrushes on oral hygiene in mentally handicapped population was investigated.</td>
<td>23 moderately mentally handicapped patients were selected. Subjects divided into study and control groups. Plaque and gingival indices were scored at day 0, after 1 week, after 4 weeks and finally after 12 weeks.</td>
<td>This study indicated that electric toothbrushes may be a valuable tool for moderately mentally challenged adults who are able to brush their teeth themselves. However the lack of significant differences between groups contradicts any superiority of electric toothbrushes compared with normal brushes.</td>

<td>Bratel J., Berggren U. Long term oral effects of manual or electric toothbrushes used by mentally handicapped adults. Clin Prev Dent 1991; 13: 5-7. [16].</td>
<td>To investigate the long term oral effects in mentally handicapped patients using an electric toothbrush as compared to manual brushing. 23 moderately mentally handicapped patients were selected and sampled into two study and two control groups. Study group used electric toothbrushes while the control group used manual toothbrushes. Plaque and gingival indexes were scored at day 0, after 3 months and after 16 months. No significant changes were found in or between the groups regarding plaque scores. Thus the study concluded that an electric toothbrush is not superior to a manual toothbrush.</td>

<td>Sachin Goyal , Betsy S. Thomas, Khandige Mahalinga Bhat, G. Subraya Bhat. Manual toothbrushing reinforced with audiovisual instruction versus powered tooth brushing among institutionalized mentally challenged subjects-A randomized cross-over clinical trial: Med Oral Patol Oral Cir Bucal. 2011:16 359-64. [17].</td>
<td>To assess and compare the effectiveness of manual tooth brushing reinforced with audiovisual instructions with powered tooth brushing among the institutionalized mentally challenged individuals under supervision of trained caretakers. A randomized cross over clinical trial of 6 month duration which included 16 subjects consisting of two phases of 3 months, for each of the two groups. In group-A subjects were given manual toothbrushes with audiovisual aid followed by powered toothbrushes and vice versa for group-B. All the subjects were instructed by trained care takers. An evaluation of the plaque and gingival scores was done at the end of 1, 2 &amp; 3 months for both the groups. For mentally challenged individuals manual toothbrushes reinforced with audiovisual instructions for brushing may be comparable to the use of powered toothbrushes.</td>

<td>To evaluate the efficacy of plaque removal of three different toothbrushes on mentally disabled children in two different age groups. 15 children aged 6-12 and 15 children aged 13-18 with mild mental disabilities participated in the single blind clinical study. After 1 week of application the Quigley hein plaque index and the proximal plaque index were used to assess the oral hygiene status of each participant. This was followed by a week of recess before each group switched to next type of toothbrush. The study indicated that the electric toothbrush is the most effective for removing dental plaque in mentally disabled children.</td>

To compare the effect of electric and manual toothbrush in oral hygiene of mentally retarded children

11.

To determine the oral health status and investigate the association of oral health status with various socio demographic (age, gender, parent’s education, income) and clinical variables (etiopathology of mental disability and IQ level) among mentally disabled subjects.

12.

To evaluate the oral hygiene status of disabled children and young adults attending special schools in south canara, karnataka, India.

13.

To assess and compare the effectiveness of manual and powered toothbrush on the oral health and microbial status of mentally challenged individuals.

14.

The aim of this study was to assess the oral health status of mentally retarded adolescents in Chennai city, Tamil Nadu, India.

The study concluded that Powered toothbrush was more effective than manual toothbrush in reducing plaque levels and microbial count in the mentally challenged individuals. The Colgate 360 tooth brush is advisable to mentally challenged individuals.

15.

The aim of this study is to assess the periodontal health status and its determinants among a group of mentally disabled children in Khar-toum State and to compare it with a control group of children of normal intelligence.

NT Hashim, B Gobara, I Ghandour. Periodontal Health Status of A Group of (Non- Institutionalized) Mentally Disabled Children in Khar-toum State

The oral hygiene status is poor and inadequate among the mentally challenged adolescents, and hence, meticulous training and awareness programs need to be initiated to address this concern

16.

To compare the efficacy of powered toothbrushes in improving gingival health and reducing salivary red complex counts as compared to manual toothbrushes, among autistic individuals.

Mayuri Vajawat, PC. Deepika\^, Vijay Kumac\^, and P. Rajeshwari; A clinicomicrobiological study to evaluate the efficacy of manual and powered toothbrushes among autistic patients

17.

The results showed that brushing with the electric toothbrush over a period of three weeks significantly reduce plaque, calculus and gingivitis index when compared with manual toothbrush.

The study sample comprised of 225 mentally retarded subjects aged 12-30 yrs, caries status, oral hygiene status and periodontal status were assessed by DMFT index, Simplified Oral hygiene index and community periodontal index.

The present study highlighted that the oral health status of mentally retarded population was poor and was influenced by etiology of disability, IQ level and patient’s level of education.

11.

To assess and compare the effect of manual and powered toothbrush in oral hygiene status and community periodontal index.

17.
Conclusion

The oral health of these groups must be improved and a suitable system devised for delivery of preventive measures. Special consideration must be given to improve the oral health of these groups. Oral health should be included in each child’s individual health care plan. Oral health promotion programmes should be aimed specifically at special needs schools and their parents. All these groups should be educated in how to maintain proper oral hygiene. Children should be instructed to clean their teeth twice a day and oral hygiene should be practised at school and supervised by teachers. There should be a provision for in-service training for teachers, school staff and parents on how to promote good oral health specifically for these children with disabilities.
