Abstract

The testis sparing surgery is a safe and feasible procedure for patients with small testicular masses, which are defined in literature as not palpable and/or <2 cm in diameter masses, and may be benign in 80% of cases. We report our experience on TSS of one patient with small testicular nodules, that was diagnosed as an adenomatoid tumor.

Keywords: testis sparing surgery, small testicular masses, adenomatoid tumor, testicle tumor.

Introduction

The testis sparing surgery (TSS) was proposed in 1986 thanks to Stoll [1], and due to the increasing use of imaging exams (US, MRI and CT) and frozen section examination (FSE), the technique is became more common in the field of surgery for incidental small masses and more safe for the patients. The TSS is particularly useful in the small testicular masses (STM), which are defined in literature as not palpable and/or <2 cm in diameter masses, and may be benign in 80% of cases [2].

We report our experience on TSS of one patient with small testicular nodules, that was diagnosed as an adenomatoid tumor thanks to the frozen section examination. The surgical technique used differs slightly from the technique described by Goldstein, and it is described in the following article [2] (Figure 1).

Case presentation

A 54 year-old patient complained pain and a palpable small mass in the right testis. There were no other genitourinary symptoms and the past medical history was negative for other pathologies. At the clinical examination a 1 cm round, painful, not tender mass was confirmed on the right side in the tail of epididymis. Bilateral hydrocele was revealed, scrotal skin, spermatic cords, and the other testis were completely normal. During the examination an ultrasonography of the testis was performed. US showed the hypoechoic small mass (1 X 1 cm) in the tail of the epididymis. The laboratory investigations were performed and testicular tumor markers beta –HCG, alfa-feto protein and LDH were within the normal limit. An MRI was also achieved. The imaging showed an oval mass in contiguity to the right tail of epididymis with a maximum diameter of about 0.8 cm, hypo-isointense with the didymus
Figure 1: 0.8 cm oval mass in contiguity to the tail of right epididymis, hypo-isointense with the didymus in T2 sequences (coronal section).

Figure 2: 0.8 cm oval mass in contiguity to the tail of right epididymis, hypo-isointense with the didymus in T2 sequences (sagittal section).

Discussion

Testis-sparing surgery may be performed for benign <2 cm lesions such as adenomatoid tumor, teratoma, Leydig cell tumor, and epidermoid cyst based on imaging characteristics and frozen biopsy findings [1]. The TSS should be mandatory performed together with frozen section examination because cancer can be present even in very small masses (<1 cm) or in not palpable masses, so if a cancer is detected an orchidectomy will be the right therapeutic choice. In benign masses the TSS avoids unnecessary radical intervention, so from reduce psychosocial consequences related to a modified body-image, and save endocrinial function to avoid hypogonadism and infertility [3]. A meticulous clinical and instrumental evaluation, with US or MRI, allow an accurate selection of patient eligible for organ-preserving surgery. After a literature revision, we have collected a total of 20 cases of Adenomatoid tumor treated with TSS. Table 1 summaries some notable characteristics of patients undergoing this type of surgery. As the table shows, TSS is a technique performed in different areas of the world, and can be

Easily and safely performed in case of negative tumor markers and after an imaging stadiation (US or MRI). Aspiration cytology was reported only in two patients.

In our case, patient has a common presentation of adenomatoid tumor from the tail of the epididymis associated with scrotal pain. The clinical examination, negative markers and imaging investigations were probative for a diagnosis of adenomatoid tumor. Although clinical and radiological investigations are able to distinguish some benign lesions, to be certain of the best treatment a Testis-sparing surgery with frozen section examination must be planned, so as to confirm the benign origin of the mass during the surgical procedure; although clinical and radiological investigations are able to distinguish some benign lesions.
